

☒ : This is a video of a golf shot. Please predict whether the golf ball will go into the hole based on its observed trajectory. Answer Yes or No.

✦ : Analyzing Jenga Stability. I'm currently dissecting the visual data, specifically focusing on a hand's indication of a blue block on the tower's base. My analysis is progressing to understand the structural implications of this targeted block within the bottom layer, which appears to have three blocks. Refining Layer Structure. My attention has shifted to refining the details of the bottom layer. I've identified the blue block as the target and am now confirming its precise position and the supporting pink block. The initial impression of a three-block base was incorrect; it's a two-block configuration, which significantly impacts the stability analysis upon the blue block's removal. Evaluating Block Interaction. I'm now focusing on the interaction between the hand and the central blue block. My current thinking is that the finger is indicating the block as the target for removal. This leads me to analyze if the hand is pushing or pointing. Revising Base Configuration. I'm revisiting the initial layer assessment. My previous thought about a two-block base was incomplete; I now see a pink block on the right and a central blue block. Crucially, the left block appears to be missing, and the layer above is oriented differently. Assessing Structural Imbalance. I'm now considering the implications of the identified gap on the left of the bottom layer. My analysis suggests that removing the central blue block, as indicated by the hand, will destabilize the tower. The remaining pink block on the right won't adequately support the shifted center of gravity. Based on the visual evidence, the bottom layer of the tower currently consists of only two blocks: the blue one in the middle and a pink one on the right. The block on the left side is already missing. If the hand removes the middle blue block, the entire weight of the tower will be supported solely by the single pink block on the far right. Because the center of mass of the tower is located roughly in the middle (where the blue block currently is), removing this central support will cause the tower to become completely unbalanced and immediately collapse to the left. Therefore, the tower will not remain stable. No. ❌

✨ : Looking at the sequence of images, I can see a Jenga tower made of pink/red and blue blocks. A hand is approaching from the left side and appears to be reaching toward one of the lower blocks in the tower. The hand seems to be pointing at or attempting to pull a block from near the bottom of the tower. The tower appears to be relatively stable throughout all the frames, it doesn't appear to be leaning significantly or showing signs of collapse. Looking at the block being targeted, it appears to be one of the lower blocks. The tower remains standing throughout all 16 frames, suggesting that either the block hasn't been fully removed yet, or the tower remains stable. Since the tower appears stable throughout all frames and doesn't show any signs of toppling, I'll predict that the tower will remain stable. Yes. The tower will remain stable after the block is removed. The hand appears to be targeting a block near the base of the tower, but the tower maintains its structural integrity throughout the sequence of frames. The tower shows no significant leaning or instability, and the weight distribution appears well-balanced enough to support the structure even after the block's removal. ✅

🌀 : Assessing block stability. I'm looking at the blue block, which is positioned center-bottom between pink blocks on the same layer. If it's pushed from the left, the whole setup could shift right and topple. This blue block seems to be middle in a three-block row at the bottom. If I remove it, two outer blocks may keep the tower stable, but I still need to evaluate the center of mass and overall support. The structure is quite irregular but somewhat centered. Examining block stability. It looks like the finger is underneath a pink block on the second row, while the blue block is sandwiched below another pink slab. They chose a block that's flush with the front, making it easy to push, but if the tower were unstable, it could collapse quickly. Still, there's no noticeable tilt when pushing. If I remove the bottom-center support in a Jenga setup, the two outer blocks might remain stable. I'll check the top center relative to the base to see if it maintains balance. Confirming block position. I want to double-check that the targeted block isn't actually to the left of center. My finger is touching the left end of a blue block that's visible, and it seems to be the center block in the bottom row, with a little bit protruding. So, it looks like the answer is Yes. I just need to express that simply with a Yes or No. Yes. ✅
